astronomy is a wonderfully dynamic science. as we look farther and farther from earth and explore the deep space and the planets, we also find that the laws of physics don't stop changing. over the past few centuries, the placement of stars in the sky has moved, and our understanding of the way stars work has changed. discoveries have shaped our understanding of the

---

universe and the meaning of life. astronomy is exciting. it's a continuous process of discovery. the night sky has been viewed as a barrier to astronomy since ancient times. in the united states, the passage of the commercial space act in 1958 put an end to the legal impediment for the first time. this act applied to the then "closed" skies of the united states and other western countries; after this event, other countries moved into a "public" domain of observation. after 1958, similar laws were passed in other western countries, and the sky barrier is being lifted still further throughout the

---

world. in many parts of the world, space observations are no longer hampered by law, and sky observability is being expanded to the point that the number of astronomical observatories is increasing rapidly. redshift is a measure of the doppler effect experienced by light emitted by an object. the effect is defined as the ratio of the observed redshift to the actual velocity of the object. this is the same as saying that redshift is the frequency (or wavelength) of light emitted at the time of observation divided by the frequency (or wavelength) emitted at the time of a reference measurement.

---

more precisely redshift is defined as one part of the observed spectrum of a source of light which moves away from us. the redshift is only really significant when the observer is looking at the source at angles of around 50 degrees or more, otherwise the light is blurring out and the redshift is too small to be measured.

The recombination of light is the point at which free electrons in space recombine with other electrons that have become ionized by their surrounding radiation and

---

rejoin the neutral state of the atom that they were once part of. Recombination happens when photons of a certain wavelength are present. The recombination wavelength depends on the original neutral state of an atom, or the energy level it was in, and on the amount of ionized electrons present. When the light is redshifted, its energy (a given energy level) is moved closer to the recombination wavelength, so that photons with higher energies have lower frequencies. redshift a measure of the doppler effect experienced by light emitted by an object. the effect is defined as the ratio of the

---

observed redshift to the actual velocity of the object. this is the same as saying that redshift is the frequency (or wavelength) of light emitted at the time of observation divided by the frequency (or wavelength) emitted at the time of a reference measurement. redshift is the observed shift in wavelength (or frequency) of light from a source as it is observed moving away from the observer. the observed redshift can be between 0 and 100 per cent. the more that the wavelength or frequency of light is shifted towards longer or shorter wavelengths, the greater the observed redshift. redshift

---

indicates that an object is moving away from the observer because the wavelength of light from the object is longer than the wavelength of light from the source of light. redshift results in a decrease in the energy of the light wave. shift in the wave is the same as blueshift. redshift is inversely proportional to frequency of light. the effect of the doppler effect is also known as doppler shift. high-speed objects like meteors exhibit a great doppler shift.
