I want to handle any problems as soon as possible. What is the best way to handle a situation where the slave has moved out of sync? Should I create a new slave, or should I fail over the master to the slave? Or is there a better way to do this that I haven't thought of? Note that this is a real-time replication, so I need a solution that will replicate a couple of seconds (or minutes) before taking action. A: The best and proper way is to detect the inconsistency and failover to the slave so that the correct data is available when the user makes an update. The process for doing this varies from one RDBMS to another and is proprietary to each vendor. We typically do this with what we call SQL sequence triggers. When there is an update on the master that breaks the sequence, we mark the last entry as the wrong one so that the next update from the master will be replicated and the user can see the correct data. A: RDMBS has built-in functionality to do this. For example, in MYSQL/MariaDB, when a master node receives a STOP SLAVE; it will first check the binlog position of the slave. From there, the master will start from the latest position and execute as many statements as required until it is completely up to date with the master database. There is no sense in making a slave node failover to the master if the slave has a bit-for-bit copy of the data.
